Abstract

The aim of this research is to measure the concentrations of radon gas for nine kinds of imported fertilizers samples that are widely used due to what they can cause of an increment in natural radioactive level of soil, and that will affect the increase in the environmental contamination level with radiation.

The results of the research show, the concentrations of radon gas $C_{Rn}$ ranges from 161.9-251.98 Bqm$^{-3}$ with the average value 208.01±32.8 Bqm$^{-3}$, the surface exhalation rates for radon gas $Ex(s)$ ranges from 0.249-0.388 Bqm$^{-2}$h$^{-1}$ with the average value 0.320±0.06Bqm$^{-2}$h$^{-1}$, the mass exhalation rates for radon gas $Em$ ranges from 0.183-0.285 Bqkg$^{-1}$h$^{-1}$ with the average value 0.235±0.04Bqkg$^{-1}$h$^{-1}$, the concentrations of radium gas $C_{Ra}$ ranges from 0.365-0.57 Bqkg$^{-1}$ with the average value 0.47±0.07 Bqkg$^{-1}$ and alpha index $I_{\alpha}$ ranges from 0.0018-0.0029 with the average value 0.0023±0.0004.

From these results, the highest existence of a significant increase in the concentrations of radon gas in mono-ammonium phosphate Jordan1 sample, but the lowest concentration of radon gas in ammonium phosphate Iran sample.

Key words
Radon, exhalation rate, phosphate, fertilizer, soil.

Introduction
It is well known that traces of radionuclides are found in air, soil, water and human bodies, we inhale and ingest radionuclides every day of our lives and radioactive materials have been ubiquitous on earth since its creation. The presence of natural radioactivity in soil results in internal and external exposure to humans. Radioactive nuclides which can be found in nature are generally categorized in two distinct families, namely of arising from either "cosmogenic" or "terrestrial" origin. The most commonly encountered radionuclides that irradiate the human body through external exposure (primarily by gamma radiation) are 238U, 235U and 232Th and their subsequent radioactive decay products and 40K [1].

Nuclei can undergo a variety of processes which result in the emission of radiation. The most common forms of nuclear radiation are alpha, beta particles (negative and positive) and gamma-rays, our bodies contain radioactive materials such as 14C and 40K [2].

Although it is generally agreed that fertilizers come in two physical forms liquid and solid. The term liquid fertilizer applies to anhydrous ammonia, aqua ammonia, N solutions and liquid mixed fertilizers. Liquid N-P-K fertilizers are also known as fluid fertilizer they include true solutions which require no agitation and suspensions or slurry type mixtures of N, P and K, which require constant stirring to keep the solids suspended in the solution [3].

Collection of the samples
Nine samples of fertilizer were collected from many national marked from Baghdad city as shown in Table 1.

Experimental procedure
The determination of the radon gas concentrations in fertilizer samples were performed as follows, all samples were kept for one month before measurements in order to achieve the secular equilibrium for \(^{222}\)Rn and its daughters with their respective progenies, and were performed using the nuclear track detector CR-39 of thickness of 500\(\mu\)m. The weight of the sample was about 5g and the detectors area were about 1\(\times\)1cm\(^2\), thin filter was used in order to prevent thoron gas from reaching the detector, however, leaving the radon gas to reach the detector, as shown in Fig.1.

![Fig.1: Sealed-cup (can) technique used for fertilizer sample.](image)

Chemical etching process
The damaged track can be revealed through chemical etching of the material in the detector. The optimized etching conditions for CR-39 detectors were found to be 6.25 normality of sodium hydroxide NaOH solution at 60°C temperature for 6 hours [4]. Therefore, to prepare one normal solution, 1g of NaOH is dissolved in one liter of distilled water one molecular weight of NaOH can be obtained as follows:
The atomic weights of Na = 23 g/mol, O= 16 g/mol and H= 1g/mol. thus, the molecular weight of NaOH = 23 + 16 + 1 = 40 g/mol. therefore, 40 g of NaOH dissolved in 1 liter of distilled water gives 1 N solution of NaOH hence, NaOH 6.25\(\times\)40 dissolved in 1 liter of distilled water gives 6.25 N solution of NaOH [5].
The etching compartment has a volume of about one liter which contains 250 g of NaOH solution with 6.25N. The condenser tube is a closed assembly except for a small vent at the top, which prevents any change of etchant normality (concentration) during the experiment as a result of evaporation. The CR-39 detectors were placed in the etching solution as shown in Fig. 2.
Measurements of tracks density

The tracks density was measured using this relation:

\[
\text{Tracks density (} \rho \text{)} = \frac{\text{Average number of total pits(track)}}{\text{Area of field view}}
\]  

(1)

After the irradiation time 30 days, the tracks density was recorded using an optical microscope with a magnification of 400 x. The density of the alpha particles tracks (\(\rho\)) in the samples were calculated according to relation 1.

The radon gas concentration in fertilizer samples were obtained by the comparison between track densities registered on the detectors of the sample and that of the standard samples, using the relation [6]:

\[
C_X = \rho_X \times \left(\frac{C_S}{\rho_S}\right)
\]  

(2)

where:

- \(C_X\): is the radon gas concentration in the unknown sample.
- \(C_S\): is the radon gas concentration in the standard sample.
- \(\rho_X\): is the track density of the unknown sample (track/mm\(^2\)).
ρ\textsubscript{S}: is the track density of the standard sample (track/mm\textsuperscript{2}).

The unknown concentration was obtained using the following relation:

\[
\text{standard uranium weight (known)} \times \text{concentration (known)} = \text{weight of the sample (known)} \times \text{unknown concentration}.
\]

Fig. 4 represents the obtained calibration curve for standard samples.

\[
\begin{align*}
\text{Slope} &= 12.235 \text{ (track.m}^3\text{/Bq. mm}^2\text{)} \\
R^2 &= 0.96197
\end{align*}
\]

\textbf{Fig. 4: The relation between radon gas concentration and track density in standard samples [7].}

The effective radium content C\textsubscript{Ra} in samples were calculated as; [8]:

\[
C_{Ra} = \frac{\rho \text{h} \cdot A}{k \cdot M \cdot T_e} \quad (3)
\]

where h: the distance from the sample to CR-39 detector.
A: the area of the cup.
K: the calibration factor which is equal to (3.9816 tracks.mm\textsuperscript{-2}.d\textsuperscript{-1}/Bq.m\textsuperscript{3})

T\textsubscript{e}: the effective time calculated as:

\[
T_e = \left[ T - \frac{1}{\lambda_{Rn}} \log \left( 1 - e^{-\lambda_{Rn}T} \right) \right]
\]

T: exposure time.

The radon exhalation rate in terms of area \( E_x \) (Bq.m\textsuperscript{-2}.h\textsuperscript{-1}) was calculated as follows [8, 9]:

\[
E_x = \frac{CV\lambda}{A[T + \frac{1}{\lambda} \left( e^{-\lambda T} - 1 \right)]]} \quad (4)
\]

where C: the integrated radon exposure measured by the CR-39 SSNTD (Bq.m\textsuperscript{-3}.h).
V: the effective volume of the container (m\textsuperscript{3}).
\lambda: the decay constant of radon (h\textsuperscript{-1}).
T: the exposure time (h), and A is the area covered by the container (m\textsuperscript{2}).

The radon exhalation rate in terms of mass \( E_m \) (Bq kg\textsuperscript{-1}.h\textsuperscript{-1}) was calculated as:

\[
E_m = \frac{CV\lambda}{M[T + \frac{1}{\lambda} \left( e^{-\lambda T} - 1 \right)]]} \quad (5)
\]

where M is the mass of the sample (kg), the alpha index was calculated as [10].

\[
I_{\alpha} = \frac{C_{Ra}}{200} \quad (6)
\]

Finally the concentrations of radon gas in fertilizer samples are shown in Table 2.

\textbf{Results}

Fig. 5 shows the lowest of radon concentration was found in (S8) is equal to (161.9Bqm\textsuperscript{-3}), the highest of radon concentration was found in (S3) is equal to (251.98Bqm\textsuperscript{-3}) and the average value is equal to (208.01±32.8Bqm\textsuperscript{-3}).

Fig. 6 shows the lowest of surface exhalation rate was found in (S8) is equal to (0.249Bq m\textsuperscript{-2}.h\textsuperscript{-1}), the highest
of surface exhalation rate was found in (S3) is equal to (0.388 Bq m\(^{-2}\) h\(^{-1}\)) and the average value is equal to (0.320±0.06 Bq m\(^{-2}\) h\(^{-1}\)).

Fig. 7 shows the lowest of mass exhalation rate was found in (S8) is equal to (0.183 Bq kg\(^{-1}\) h\(^{-1}\)), the highest mass exhalation rate was found in (S3) and equal to (0.285 Bq kg\(^{-1}\) h\(^{-1}\)) and the average value is equal to (0.235 ± 0.04 Bq kg\(^{-1}\) h\(^{-1}\)).

Fig. 8 shows: the lowest of radium concentration was found in (S8) is equal to (0.365 Bq kg\(^{-1}\)), the highest of radon concentration was found in (S3) is equal to (0.57 Bq kg\(^{-1}\)) and the average value is equal to (0.47 ± 0.07 Bq kg\(^{-1}\)).

Fig. 9 shows the lowest of alpha index was found in (S8) and equal to (0.0018), the highest of alpha index was found in (S3) equal to (0.0029) and the average value is equal to (0.0023 ± 0.04 x 10\(^{-4}\)).

These results shows that, the average values of radon gas concentration \(C_{Rn}\) in fertilizer samples (208.01±32.8 Bq m\(^{-3}\)) greater than the value of the global limit (200 Bq m\(^{-3}\)), and the averages radiological hazard index (\(C_{Ra}\), \(E_x\), \(E_m\) and \(I_\alpha\)) in fertilizer samples are, (0.47±0.07 Bq kg\(^{-1}\), 0.320±0.06 Bq m\(^{-2}\) h\(^{-1}\), 0.235±0.04 Bq kg\(^{-1}\) h\(^{-1}\) and 0.0023±4x10\(^{-4}\)) respectively.

Fig. 5: Concentrations of radon gas for fertilizer samples.

Fig. 6: Surface exhalation rate for fertilizer samples.

Fig. 7: Mass exhalation rate for fertilizer samples.
Conclusions
The maximum value of radon concentration in fertilizer samples was found in Ammonium phosphate (MAP) Mono-Jordan which made in Jordan and gives a large value of \(C_{Ra}, E_{x}, E_{m} \text{ and } I_{\alpha}\), the highest radon concentration in fertilizer samples was found in Ammonium phosphate (MAP) Mono-Jordan equal to \((251.98Bq/m^3)\), the reason of the highest concentration may be that the fertilizer containing high concentrations of uranium. The average of radon gas concentration was greater than the global limit \((200Bq/m^3)\).
